

DFS DISCOVERS COMPONENTS

- Note: DEPTH-FIRST-SEARCH calls DFS repeatedly.
- DFS (inner function) calls itself on unseen neighbors.
- Theorem: If DFS is started on vertex v then it will finish all the vertices in the connected component of v before terminating.

<https://tutorcs.com>

- Proof:
 - Suppose for contradiction that a vertex in the v 's component is not visited.
 - Let u be the unvisited vertex that is the fewest hops away from v

- w must have been visited, and from there u . Contradiction!

TYPES OF EDGES IN DFS EXPLORATION

Tree edges: edges on which new vertices are discovered

Back edges: all other edges

THE DFS TREE

- G is a connected graph and we start depth-first search at node v .
- Tree edges actually form a tree rooted at v .
- There is a unique path from v to every vertex in tree.
- Structure of tree = recursive structure of DFS.
 - If x is parent of y then $\text{DFS}(x)$ calls $\text{DFS}(y)$
 - $\text{DFS}(y)$ finishes before $\text{DFS}(x)$
 - Z is a descendant of x if it lies in subtree rooted at x (x is an ancestor of Z)
 - Define $s(x), f(x)$: start and finish time of x
 - Z descendant of $x \Leftrightarrow s(x) < s(z) < f(z) < f(x)$

ONE MORE OBSERVATION:

“NO STONE UNTURNED”

- Suppose we are starting $\text{DFS}(v)$.
- Suppose:
 - There is a path P from v to u .
 - Every vertex on P is unseen at the moment.
- Then u will become a descendant of v in the DFS tree.
- Proof: Similar to the proof that DFS started at a vertex will discover every vertex in the component.

ABOUT BACK EDGES

- Back edges always go between descendants and ancestors in DFS Tree.
- Why?

- Suppose (u, v) is a back edge.
- Say u was discovered before v (no loss of generality here).
- (u, v) must be tried before $\text{DFS}(u)$ finishes.
- v must be discovered before $\text{DFS}(u)$ finishes.
- So v is a descendant of u .
- (u, v) goes between ancestor and descendant.
